$x^{2} \frac{d^{2} y}{d x^{2}}-3 x \frac{d y}{d x}+3 y=0, x>0$
with $y(x)$ as a general solution. Given that $y(1)=1$ and $y(2)=14$ the value of $y(1.5)$, rounded off to two decimal places, is
50. The RC circuit shown below has a variable resistance $R(t)$ given by the following expression :

$$
R(t)=R_{0}\left(1-\frac{t}{T}\right) \text { for } 0 \leq \mathrm{t}<\mathrm{T}
$$

where $R_{0}=1 \Omega$, and $C=1 \mathrm{~F}$. We are also given that $T=3 R_{0} C$ and the source voltage is $\mathrm{V}_{\mathrm{s}}=1 \mathrm{~V}$. If the current at time $\mathrm{t}=0$ is 1 A , then the current $\mathrm{I}(\mathrm{t})$, in
amperes, at time $\mathrm{t}=\mathrm{T} / 2$ is (rounded off to 2 decimal places).

51. In the circuit shown, $\mathrm{V}_{\mathrm{s}}$ is a 10 V square wave of period, $T=4 \mathrm{~ms}$ with $\mathrm{R}=500 \Omega$ and $C=10 \mu \mathrm{~F}$. The capacitor is initially uncharged at $\mathrm{t}=0$, and the diode is assumed to be ideal. The voltage across the capacitor $\left(\mathrm{V}_{\mathrm{c}}\right)$ at 3 ms is equal to
$\qquad$ volts (rounded off to one decimal place).

52. Consider the line integral

$$
\int_{C}(x d y-y d x)
$$

the integral being taken in a counterclockwise direction over the closed curve $C$ that forms the boundary of the region $R$ shown in figure below. The region $R$ is the area enclosed by the union of a $2 \times 3$ rectangle and a semi-circle of radius 1 . The line integral evaluates to

A. $16+2 \pi$
B. $8+\pi$
C. $12+8 \pi$
D. $6+\pi / 2$
53. Consider a unity feedback system, as in the figure shown, with an integral compensator and open-loop transfer function

$$
G(s)=\frac{1}{s^{2}+3 s+2}
$$

Where $\mathrm{K}>0$. The positive value of K for which there are exactly two poles of the unity feedback system on the $j \omega$ axis is equal to $\qquad$ (rounded off to two decimal places).

54. A voice signal $m(t)$ is in the frequency range 5 kHz to 15 kHz . The signal is amplitude-modulated to generate an $A M$ signal $f(t)=A(1+m(t)) \cos 2 \pi f_{c} t$, where $f_{c}$ $=600 \mathrm{kHz}$. The $A M$ signal $f(t)$ is to be digitized and archived. This is done by first sampling $f(t)$ at 1.2 times the Nyquist frequency, and then quantizing each sample using a 256 -level quantizer. Finally, each quantized sample is binary coded using K bits, where K is the minimum number of bits required for the encoding The rate, in Megabits per second (rounded off to 2 decimal places), of the resulting stream of coded bits is $\qquad$ Mbps.
55. A single bit, equally likely to be 0 and 1 , is to be sent across an additive white Gaussian noise (AWGN) channel with power spectral density $N_{0} / 2$. Binary signaling, with $0 \rightarrow p(t)$ and $1 \rightarrow q(t)$, is used for the transmission, along with an optimal receiver that minimizes the biterror probability.
Let $\varphi_{1}(\mathrm{t}), \varphi_{2}(\mathrm{t})$ form an orthonormal signal set.
If we choose $p(t)=\varphi_{1}(t)$ and $q(t)=-$ $\varphi_{1}(\mathrm{t})$, we would obtain a certain bit-error probability $\mathrm{P}_{\mathrm{b}}$.
If we keep $p(t)=\varphi_{1}(t)$, but take $q(t)=\sqrt{ } E$ $\varphi_{2}(\mathrm{t})$, for what value of E would we obtain the same bit-error probability $\mathrm{P}_{\mathrm{b}}$ ?
A. 3
B. 2
C. 0
D. 1
